The tight-binding model is opposite limit to the nearly free electron model. The potential is so large that the electrons spend most of their lives near ionic cores, only occasionally shift to nearest core atom quantum mechanically.

The nearly free electron method looks at the wave-functions outside the atomic cores, where they look very like plane waves. Within the cores they look like atomic orbitals. This suggests an entirely different scheme for the construction of electron wave-functions: we try to combine atomic orbitals, each localized on a particular atom, to represent a state running throughout the crystal.

1. One dimensional case: Bloch theorem

Suppose that the electrons are tightly bound to the nuclei. The wavefunction would coincide within the $n$ cell, with an atomic eigenfunction $\phi_a$ (such as 1s, 2s, 2p, ...). Then the wavefunction of the system may be expressed by a linear combination of atomic orbital (LCAO) function,

$$\psi_k(x) = \frac{1}{\sqrt{N}} \sum_{n=1}^{N} C_n \phi_a(x - na).$$
The coefficient \( C_n \) can be determined as
\[
C_n = e^{i k a n},
\]
from the requirement that \( \psi_k(x) \) should be the Bloch wave function;
\[
\psi_k(x + a) = e^{i k a} \psi_k(x).
\]
((Proof))
Since
\[
\psi_k(x + a) = \frac{1}{\sqrt{N}} \sum_{n=1}^{N} C_n \phi_n(x + a - na) = \frac{1}{\sqrt{N}} \sum_{j=1}^{N} C_{j+1} \phi_n(x - ja),
\]
\[
e^{i k a} \psi_k(x) = \frac{1}{\sqrt{N}} e^{i k a} \sum_{j=1}^{N} C_j \phi_n(x - ja),
\]
we get the relation
\[
C_{j+1} = e^{i k a} C_j.
\]
When \( C_1 = e^{i k a} \), \( C_n \) is obtained as
\[
C_n = e^{i k a n}.
\]
Then we have the Bloch wave as
\[
\psi_k(x) = \frac{1}{\sqrt{N}} \sum_{n=1}^{N} e^{i k a n} \phi_n(x - na).
\]
((Note)) It is also clear that this form of \( \psi_k(x) \) satisfies the Bloch theorem,
\[
\psi_k(x) = \frac{1}{\sqrt{N}} e^{i k x} \sum_{n=1}^{N} e^{-i k(x-na)} \phi_n(x - na) = e^{i k x} u_k(x),
\]
where
\[
u_k(x) = \sum_{n=1}^{N} e^{-i k(x-na)} \phi_n(x - na).
\]
\( u_k(x) \) is a periodic function with a lattice period \( a \),
$$u_k(x+a) = \sum_{n=1}^{N} e^{-i k \cdot [(x-(n-1)a)]} \phi_n \left[ x-(n-1)a \right] = u_k(x).$$

It can be easily shown that $\psi_k(x)$ possesses all the required properties of the Bloch waves,

$$\psi_{k+G}(x) = \sum_{n=1}^{N} e^{i k n a} e^{iGn a} \phi_n \left( x-na \right) = \sum_{n=1}^{N} e^{i k n a} \phi_n \left( x-na \right) = \psi_k(x).$$

((Note)) **Validity of the choice of above wave function**

From the Bloch theorem, we have

$$\psi_k(x) = e^{ikx} u_k(x)$$

We choose $u_k(x)$ as

$$u_k(x) = \sum_{n} \phi_n \left( x-na \right)$$

we note that $\phi(x-na)$ is a wave function localized at $x=na$ [like a Dirac delta function $\delta(x-na)$]. It is clear that $u_k(x)$ is periodic such that

$$u_k(x+a) = \sum_{n} \phi_n \left( x+a-na \right) = \sum_{n} \phi_n \left[ x-(n-1)a \right] = u_k(x)$$

We note that

$$\psi_k(x) = e^{ikx} u_k(x)$$

$$= \sum_{n} e^{ikx} \phi_n \left( x-na \right)$$

$$\approx \sum_{n} e^{ikn a} \phi_n \left( x-na \right)$$

In general case (3D system)

$$\psi_k(r) = e^{i k \cdot r} u_k(r)$$

$$= \sum_{l} e^{i k \cdot r_l} \phi_a \left( r-R_l \right)$$

$$\approx \sum_{l} e^{i k \cdot R_l} \phi_a \left( r-R_l \right)$$
2. Three dimensional case

According to the Bloch theorem, we consider the wavefunction given by

$$
\psi_k(r) = \frac{1}{\sqrt{N}} \sum_{j=1}^{N} e^{ik \cdot R_j} \phi_a(r - R_j),
$$

where we assume that there is one atom per unit cell. The number of atoms is $N$.

$$
\int dr \phi_a^*(r - R_j) \phi_a(r - R_l) = \delta_{jl}.
$$

The wavefunction $\psi_k(r)$ is normalized as follows.

$$
\int dr \psi_k^*(r) \psi_k(r) = \frac{1}{N} \sum_{j,l} e^{-ik \cdot R_j} e^{ik \cdot R_l} \int dr \phi_a^*(r - R_j) \phi_a(r - R_l) = \frac{1}{N} \sum_{j,l} e^{-ik \cdot R_j} e^{ik \cdot R_l} \delta_{jl} = 1
$$

The Hamiltonian $H$ is defined by

$$
H = -\frac{\hbar^2}{2m} \nabla^2 + V(r),
$$

where $V(r)$ is the periodic potential of the present system.
Potential in the tight binding approximation. The potential $V_a(r - R_i)\) is the potential from the isolated atom at $R_i$. $\tilde{V}(r) = \sum_{j=1}^{N} V_a(r - r_j)$. $V(r)$ is a periodic potential of the system: $V(r) < \tilde{V}(r)$.

Here $V_a(r - R_i)$ is the potential of the atom isolated at the position vector $R_i$. The wavefunction $\phi_a(r - R_i)$ satisfies the Schrödinger equation,

$$\left[-\frac{\hbar^2}{2m} \nabla^2 + V_a(r - R_i)\right]\phi_a(r - R_i) = \varepsilon_a^{(0)} \phi_a(r - R_i),$$

where $\varepsilon_a^{(0)}$ is the energy eigenvalue of the isolated atom. The Hamiltonian of the system is given by

$$H = -\frac{\hbar^2}{2m} \nabla^2 + V(r)$$

where $V(r)$ is the periodic potential of the system. It is different from the potential $\tilde{V}(r)$ which is defined by

$$\tilde{V}(r) = \sum_{j=1}^{N} V_a(r - r_j)$$

and

$$V(r + R_i) = V(r), \quad \tilde{V}(r + R_i) = \tilde{V}(r)$$

We start with the eigenvalue problem with the Schrödinger equation for the Hamiltonian,

$$H \psi_k(r) = \varepsilon_k \psi_k(r),$$

Noting that

$$\tilde{V}(r)\phi_a(r - R_i) = \sum_{j=1}^{N} V_a(r - r_j)\phi_a(r - R_i)$$

$$= V_a(r - r_i)\phi_a(r - R_i)$$

we get
\[
[-\frac{\hbar^2}{2m} \nabla^2 + V(r)]\psi_k(r) = \frac{1}{\sqrt{N}} \sum_{i=1}^{N} e^{i k \cdot R_i} [\left(-\frac{\hbar^2}{2m} \nabla^2 + V(r)\right) \phi_a(r - R_i)]
\]
\[
= \frac{1}{\sqrt{N}} \sum_{i=1}^{N} e^{i k \cdot R_i} \left(-\frac{\hbar^2}{2m} \nabla^2 + \nabla \left(V(r) - \nabla V(r)\right)\right) \phi_a(r - R_i)
\]
\[
= \frac{1}{\sqrt{N}} \sum_{i=1}^{N} e^{i k \cdot R_i} \left(-\frac{\hbar^2}{2m} \nabla^2 + V_a(r - R_i)\right) \phi_a(r - R_i)
\]
\[
+ \frac{1}{\sqrt{N}} \sum_{i=1}^{N} e^{i k \cdot R_i} \left(V(r) - \nabla V(r)\right) \phi_a(r - R_i)
\]

Thus we have
\[
[-\frac{\hbar^2}{2m} \nabla^2 + V(r)]\psi_k(r) = \varepsilon_a^{(0)} \frac{1}{\sqrt{N}} \sum_{i=1}^{N} e^{i k \cdot R_i} \phi_a(r - R_i)
\]
\[
+ \frac{1}{\sqrt{N}} \sum_{i=1}^{N} e^{i k \cdot R_i} \left(V(r) - \nabla V(r)\right) \phi_a(r - R_i)
\]
\[
= \varepsilon_k \frac{1}{\sqrt{N}} \sum_{i=1}^{N} e^{i k \cdot R_i} \phi_a(r - R_i)
\]

By multiplying both sides of this equation by \(\phi^*_a(r - R_f)\) and integrating over all the space, we have
\[
(\varepsilon_k - \varepsilon_a^{(0)}) \sum_{i=1}^{N} e^{i k \cdot R_i} \int d\mathbf{r} \phi_a^*(r - R_f) \phi_a(r - R_i)
\]
\[
= \sum_{i=1}^{N} e^{i k \cdot R_i} \int d\mathbf{r} \phi_a^*(r - R_f) \left[V(r) - \nabla V(r)\right] \phi_a(r - R_i)
\]

We note that
\[
\int d\mathbf{r} \phi_a^*(r - R_f) \phi_a(r - R_i) = \delta_{i,f}
\]
(orthogonality of the wave function)

Thus we get
\[
(\varepsilon_k - \varepsilon_a^{(0)}) \sum_{i=1}^{N} e^{i k \cdot R_i} \delta_{i,f} = \sum_{i=1}^{N} e^{i k \cdot R_i} \int d\mathbf{r} \phi_a^*(r - R_f) \left[V(r) - \nabla V(r)\right] \phi_a(r - R_i)
\]

or

Thus we have
\[
[-\frac{\hbar^2}{2m} \nabla^2 + V(r)]\psi_k(r) = \varepsilon_a^{(0)} \frac{1}{\sqrt{N}} \sum_{i=1}^{N} e^{i k \cdot R_i} \phi_a(r - R_i)
\]
\[
+ \frac{1}{\sqrt{N}} \sum_{i=1}^{N} e^{i k \cdot R_i} \left(V(r) - \nabla V(r)\right) \phi_a(r - R_i)
\]
\[
= \varepsilon_k \frac{1}{\sqrt{N}} \sum_{i=1}^{N} e^{i k \cdot R_i} \phi_a(r - R_i)
\]
When we define the potential difference by

$$\Delta V(r) = V(r) - \bar{V}(r)$$

which is negative, we get

$$\epsilon_k - \epsilon_a^{(0)} = \sum_{j=1}^{N} e^{i k \cdot R_j} \left[ \int dr \phi_a^*(r - R_j) [V(r) - \bar{V}(r)] \phi_a(r - R_j) \right]$$

Note that this integral remains unchanged when the variable of the integral is changed from $r - R_j$ to $r$, since

$$\Delta V(r - R_j) = \Delta V(r).$$

Here we put

$$R_i - R_j = R_h,$$

**Fig.** Schematic form of the potential energy for tightly bound electrons, along a given direction in the crystal. (Rigamonti and Carretta, Structure of Matter, Springer, 2007).
\[ \varepsilon_k - \varepsilon^{(0)}_a = \sum_{h=1}^{N} e^{ik \cdot R_h} \int dr \phi^*_a (r + R_h) \Delta V(r) \phi_a(r) \]

When the matrix element \( t_h \) is defined by

\[ t_h = \int dr \phi^*_a (r + R_h) \Delta V(r) \phi_a(r) , \]

the energy eigenvalue is approximated by

\[
\varepsilon_k = \varepsilon^{(0)}_a + \sum_h t_h e^{ik \cdot R_h} \\
\approx \varepsilon^{(0)}_a - \alpha - \sum_{n.n.} t_{n.n.} e^{ik \cdot R_h} \\
\approx \varepsilon^{(0)}_a - \alpha - \gamma \sum_{n.n.} t_{n.n.} e^{ik \cdot R_h}
\]

The sum over \( R_h \) includes only values for which \( R_l \) denotes a nearest neighbor of \( R_j \). In the present case, both \( \alpha \) and \( \gamma \) are positive since \( \Delta V \) is negative. Note that the n.n denotes the nearest neighbor pairs.

3. 3D systems: sc, fc, and bcc
(a) Simple cubic
For the simple cubic lattice with the lattice constant $a$,

$$
\varepsilon_k = \varepsilon_a^{(0)} - \alpha - 2\gamma(\cos k_x a + \cos k_y a + \cos k_z a),
$$
Fig. ContourPlot for the constant energy surface in the reciprocal lattice space. \[ \cos k_x a + \cos k_y a + \cos k_z a = 0.75. \]

When \( |k_x a| << 1, |k_y a| << 1, \) and \( |k_z a| << 1, \) we get

\[ \varepsilon_k = \varepsilon^{(0)}_a - \alpha - 6\gamma + \gamma a^2 (k_x^2 + k_y^2 + k_z^2). \]

(b) fcc

There are twelve nearest neighbor atoms in the fcc lattice:

\[
\begin{align*}
  a_1 &= \frac{a}{2}(0,1,1), & a_2 &= \frac{a}{2}(-1,0,1), & a_3 &= \frac{a}{2}(-1,1,0), & a_4 &= \frac{a}{2}(1,0,1), & a_5 &= \frac{a}{2}(0,-1,1), \\
  a_6 &= \frac{a}{2}(1,1,0), & a_7 &= \frac{a}{2}(-1,-1,0), & a_8 &= \frac{a}{2}(0,1,-1), & a_9 &= \frac{a}{2}(-1,0,-1), & a_{10} &= \frac{a}{2}(1,-1,0), \\
  a_{11} &= \frac{a}{2}(1,0,-1), & a_{12} &= \frac{a}{2}(0,-1,-1)
\end{align*}
\]
\[ \varepsilon_k = \varepsilon^{(0)}_k - \alpha - 4\gamma \cos\left(\frac{k_x}{2}\right) \cos\left(\frac{k_y}{2}\right) \cos\left(\frac{k_z}{2}\right) + \cos\left(\frac{k_x}{2}\right) \cos\left(\frac{k_y}{2}\right) \cos\left(\frac{k_z}{2}\right) \]

Fig. ContourPlot for the Fermi surface of Copper (M. Suzuki and I.S. Suzuki).

(c) bcc

There are eight nearest neighbor atoms in the fcc lattice;

\[
\begin{align*}
    a_1 &= \frac{a}{2} (1,1,1), & a_2 &= \frac{a}{2} (-1,1,1), & a_3 &= \frac{a}{2} (1,-1,1), & a_4 &= \frac{a}{2} (1,1,-1), & a_5 &= \frac{a}{2} (-1,-1,1), \\
    a_6 &= \frac{a}{2} (-1,1,-1), & a_7 &= \frac{a}{2} (1,-1,-1), & a_8 &= \frac{a}{2} (-1,-1,-1),
\end{align*}
\]
\[ \varepsilon_k = \varepsilon_a^{(0)} - \alpha - 8\gamma \cos\left(\frac{k_x a}{2}\right) \cos\left(\frac{k_y a}{2}\right). \]

((Mathematica program for the derivation of the energy dispersion in the Appendix)).

**4. 2D system**

For the 2D square lattice, we get

\[ \varepsilon_k = \varepsilon_a^{(0)} - \alpha - 2\gamma(\cos k_x a + \cos k_y a) \]
\[ = \varepsilon_a^{(0)} - \alpha - 2\gamma \eta \]

where \( \eta \) changes between -2 and 2,

\[ \eta = \cos k_x a + \cos k_y a. \]

![ContourPlot of \( \varepsilon_k \) = constant in the tight binding approximation for the 2D square lattice (the first Brillouin zone). (\( k_x a/2\pi - k_y a/2\pi \)). For the low energy, the ContourPlot shows a circle. ContourPlot of \( \cos(2\pi x) + \cos(2\pi y) = \eta \), where \( \eta = -2 \), to 2 (\( \Delta\eta = 0.1 \)). The first Brillouin zone is denoted by the black thick line.](image)
Near the origin of the $k$-space ($|k_x a| \ll 1$ and $|k_y a| \ll 1$), we get

$$\varepsilon_k^{(0)} = \varepsilon_a^{(0)} - \alpha - 4\gamma a^2 (k_x^2 + k_y^2).$$  \text{(electron-like)}

The effective mass $m^*$ is defined as

$$m^* = \frac{\hbar^2}{2\gamma a^2}.$$

Near the zone edge ($k_x a \approx \pi$ and $k_y a = \pi$), we get

$$\varepsilon_k = \varepsilon_a^{(0)} - \alpha - \gamma[(k_x a - \pi)^2 + (k_y a - \pi)^2].$$  \text{(hole-like)}

For the 1D lattice, we get

$$\varepsilon_k = \varepsilon_a^{(0)} - \alpha - 2\gamma \cos k_x a.$$

When $|k a| \ll 1$, we get

$$\varepsilon_k = \varepsilon_a^{(0)} - \alpha - 2\gamma + \gamma a^2 k^2.$$

The effective mass $m^*$ is defined as

$$m^* = \frac{\hbar^2}{2\gamma a^2}.$$

Fig. Formation of the energy band in the tight binding approximation.
3. Summary

The following interesting conclusions may be derived from the above figures.
(a) The energy spectrum of the electrons consists of a number of allowed energy bands separated by energy gaps.
(b) The discontinuities in the energy spectrum, occur for the zone boundaries.
