1. Blundell-Blundell: Thermal Physics

Problem 22.2

The fugacity z is defined as $z = e^{\beta\mu}$. Using

$$\mu = k_B T \ln(n\lambda_{th}^3)$$

show that

$$z = n\lambda_{th}^3$$

for an ideal gas, and comment on the limits $z \ll 1$ and $z \gg 1$.

((Solution))

The chemical potential is given by

$$\mu = k_B T \ln\left(\frac{N\lambda_T^3}{V}\right) = k_B T \ln(n\lambda_T^3)$$

The fugacity z is defined as

$$z = e^{\beta\mu}.$$

Then we have

$$\ln z = \beta\mu = \ln(n\lambda_T^3),$$

leading to the relation

$$z = n\lambda_T^3 = \frac{n}{n_Q},$$

where the quantum concentration n_Q is defined by

$$n_Q = \frac{1}{\lambda_T^3} = \left(\frac{mk_B T}{2\pi\hbar^2} \right)^{3/2}.$$

For $z \gg 1$ (high density limit; $n \gg n_Q$): quantum effect (low temperatures) is dominant.

For $z \ll 1$ (low density limit: $n \ll n_Q$), classical effect (high temperatures) is dominant.

2. Blundell-Blundell: Thermal Physics

Problem 21-4

An atom in a solid has two energy levels: a ground state of degeneracy g_1 and an excited state of degeneracy g_2 at an energy Δ above the ground state. Show that the partition function Z_{atom} is

$$Z_{atom} = g_1 + g_2 e^{-\beta\Delta}$$

Show that the heat capacity of the atom is given by

$$C = \frac{g_1 g_2 \Delta^2 e^{-\beta\Delta}}{k_B T^2 (g_1 + g_2 e^{-\beta\Delta})^2}$$

A monatomic gas of such atoms has a partition function given by

$$Z_N = \frac{(Z_1)^N}{N!}$$

where $Z_1 = Z_{atom} Z_{translation}$ and $Z_{translation} = \frac{V}{\lambda_{th}^3}$ is the partition function due to the translational motion of the gas atom. Show that the heat capacity of such a gas is

$$C = N \left[\frac{3}{2} k_B + \frac{g_1 g_2 \Delta^2 e^{-\beta\Delta}}{k_B T^2 (g_1 + g_2 e^{-\beta\Delta})^2} \right]$$

((Solution))

The particle partition function of atom is

$$Z_{atom} = g_1 + g_2 e^{-\beta\Delta}$$

The internal energy

$$U_{atom} = -\frac{\partial}{\partial \beta} \ln Z_{atom} = \frac{\Delta g_2 e^{-\beta \Delta}}{g_1 + g_2 e^{-\beta \Delta}}$$

The heat capacity:

$$\begin{aligned} C_{atom} &= \frac{dU_{atom}}{dT} \\ &= -\frac{1}{k_B T^2} \frac{dU_{atom}}{d\beta} \\ &= \frac{g_1 g_2 \Delta^2 e^{-\beta \Delta}}{k_B T^2 (g_1 + g_2 e^{-\beta \Delta})^2} \end{aligned}$$

The partition function of the system including the translational motion is

$$Z_{tot} = \frac{(Z_1)^N}{N!},$$

where

$$Z_1 = Z_{atom} Z_{translation}$$

and

$$Z_{translation} = \frac{V}{\lambda_{th}^3}.$$

We note that

$$\ln Z_{tot} = N \ln Z_1 - \ln N!$$

The internal energy:

$$\begin{aligned}
U &= -\frac{\partial}{\partial \beta} \ln Z_{tot} \\
&= -N \frac{\partial}{\partial \beta} \left(\ln Z_{atom} + \ln \frac{V}{\lambda_{th}^3} \right) \\
&= -N \frac{\partial}{\partial \beta} \ln Z_{atom} + \frac{3}{2} N \frac{\partial}{\partial \beta} \ln \beta \\
&= -N \frac{\partial}{\partial \beta} \ln Z_{atom} + \frac{3}{2} N k_B T
\end{aligned}$$

where

$$\lambda_{th} = \left(\frac{2\pi \hbar^2 \beta}{m} \right)^{1/2}, \quad \ln \lambda_{th} = \frac{1}{2} \left[\ln \beta + \ln \left(\frac{2\pi \hbar^2}{m} \right) \right]$$

The heat capacity is obtained as

$$C = N \left[\frac{3}{2} k_B + \frac{g_1 g_2 \Delta^2 e^{-\beta \Delta}}{k_B T^2 (g_1 + g_2 e^{-\beta \Delta})^2} \right]$$

3. Blundell-Blundell: Thermal Physics

Problem 21-6

Show that the single-particle partition function Z_1 of a gas of hydrogen atoms is given approximately by

$$Z_1 = Z_{translation} Z_{atom} = \frac{V}{\lambda_{th}^3} e^{\beta R}$$

where $R = 13.6$ eV and the contribution due to excited states has been neglected.

((Solution))

We assume that the energy of hydrogen atom is given by $-R$. The partition function of atom is given by

$$Z_{atom} = e^{\beta R}.$$

The partition function of hydrogen atom including the translational motion is given by

$$Z_1 = Z_{atom} Z_{translation}$$

$$= e^{\beta R} \frac{V}{\lambda_{th}^3}$$

where

$$Z_{translation} = \frac{V}{\lambda_{th}^3}$$

4. Blundell and Blundell: Thermal Physics

Problem 20-8

The internal levels of an isolated hydrogen atom are given by $-\frac{R}{n^2}$, where $R = 13.6$ eV. The degeneracy of each level is given by $2n^2$.

(a) Sketch the energy levels.

(b) Show that

$$Z_{atom} = \sum_{n=1}^{\infty} 2n^2 \exp\left(\frac{\beta R}{n^2}\right)$$

Note that when $T \neq 0$, this expression for Z_{atom} diverges. This is because of the large degeneracy of the hydrogen atom's highly excited states. If the hydrogen atom were to be confined in a box of finite size, this would cut off the highly excited states and Z_{atom} would not then diverge. By approximating Z_{atom} as follows:

$$Z_{atom} = \sum_{n=1}^2 2n^2 \exp\left(\frac{\beta R}{n^2}\right)$$

i.e. by ignoring all but the $n = 1$ and $n = 2$ states estimate the mean energy of a hydrogen atom at 300 K.

((Solution))

$n = 1$, $l = 0$ (s) degeneracy = 1
total degeneracy = $2 \times 1 = 2$ (factor 2; spin degeneracy)

$n = 2$ $l = 1$ (p) degeneracy = 3
 $l = 0$ (s) degeneracy = 1
 total degeneracy = $2 \times 4 = 8$ (factor 2; spin degeneracy)

$n = 3$ $l = 2$ (d) degeneracy = 5
 $l = 1$ (p) degeneracy = 3
 $l = 0$ (s) degeneracy = 1
 total degeneracy = $2 \times 9 = 18$ (factor 2; spin degeneracy)

$$Z_{atom} = \sum_{n=1}^{\infty} 2n^2 \exp\left(\frac{\beta R}{n^2}\right)$$

where $R = 13.6$ eV. When $T = 0$, Z diverges. For $T = 300$ K, we assume that

$$Z_{atom} = \sum_{n=1}^2 2n^2 \exp\left(\frac{\beta R}{n^2}\right) = 2 \exp(\beta R) + 8 \exp\left(\frac{\beta R}{4}\right)$$

The internal energy:

$$U = -\frac{\partial \ln Z_{atom}}{\partial \beta} = -R \left(\frac{\exp(\beta R) + \exp\left(\frac{\beta R}{4}\right)}{\exp(\beta R) + 4 \exp\left(\frac{\beta R}{4}\right)} \right)$$

$$\beta R = 526.071$$

$$U = -R = -13.6 \text{ eV}.$$

5. Blundell-Blundell: Thermal Physics

Problem 22-5

If the partition function Z_N of a gas of N indistinguishable particles is given by

$$Z_N = \frac{(Z_1)^N}{N!}$$

where Z_1 is the single-particle partition function, show that the chemical potential is given by

$$\mu = -k_B T \ln \left(\frac{Z_1}{N} \right)$$

((Solution))

The partition function is given by

$$Z_{CN} = \frac{Z_{C1}^N}{N!}$$

$$\begin{aligned}
F &= -k_B T \ln Z_{CN} \\
&= -k_B T \ln \frac{Z_{C1}^N}{N!} \\
&= -k_B T (N \ln Z_{C1} - \ln N!) \\
&= -k_B T [N \ln Z_{C1} - N \ln N + N]
\end{aligned}$$

We note that

$$F = U - ST$$

$$\begin{aligned}
dF &= dU - SdT - TdS \\
&= TdS - \mu dN - SdT - TdS \\
&= -\mu dN - SdT
\end{aligned}$$

The chemical potential:

$$\mu = \left(\frac{\partial F}{\partial N} \right)_T = -k_B T (\ln Z_{C1} - \ln N) = -k_B T \ln \frac{Z_{C1}}{N}$$

where

$$Z_{C1} = \frac{V}{\lambda_{th}^3} = V n_Q$$

and

$$\frac{1}{\lambda_{th}^3} = n_Q = \left(\frac{mk_B T}{2\pi \hbar^2} \right)^{3/2}, \quad \lambda_{th} = \left(\frac{2\pi \hbar^2}{mk_B T} \right)^{1/2}.$$

6. Blundell-Blundell

Problem 22-6

(a) Consider the ionization of atomic hydrogen governed by the equation

where p^+ is a proton (equivalently a positively ionized hydrogen) and e^- is an electron. Explain why

$$\mu_H = \mu_p + \mu_e$$

Using the partition function for hydrogen atoms from Eq.(21.50), and using Eq.(22.92) show that

$$-k_B T \ln \left(\frac{Z_1^p}{N_p} \right) - k_B T \ln \left(\frac{Z_1^e}{N_e} \right) = -k_B T \ln \left(\frac{Z_1^H}{N_H} e^{\beta R} \right)$$

where Z_1^x and N_x are the single-particle partition function and number of particles for species x , and where $R = 13.6$ eV. Hence show that

$$\frac{n_e n_p}{n_H} = \left(\frac{2\pi m_e k_B T}{h^2} \right)^{3/2} \exp(-\beta R) \quad \text{(Saha equation)}$$

where $n_x = \frac{N_x}{N}$ is the number density of species x , stating any approximations you make.

Equation (22.96) is known as the **Saha** equation.

(b) Explain why charge neutrality implies that $n_e = n_p$ and conservation of nucleus implies $n = n_H + n_p$, where n is the total number density of hydrogen (neutral and ionized). Writing $y = n_p / n$ as the degree of ionization, show that

$$\frac{y^2}{1-y} = \frac{1}{n} n_Q \exp(-\beta R)$$

Find the degree of ionization at 10000 K and density 10^{20} m^{-3} .

((Solution))

Chemical reaction:

$$\mu_H = \mu_p + \mu_e$$

or

$$-k_B T \ln \left(\frac{Z_1^H}{N_H} e^{\beta R} \right) = -k_B T \ln \left(\frac{Z_1^P}{N_P} \right) - k_B T \ln \left[\frac{Z_1^e}{N_e} \right]$$

where

$$\mu_H = -k_B T \ln \left[\frac{Z_1^H}{N_H} e^{\beta R} \right], \quad \mu_P = -k_B T \ln \left[\frac{Z_1^P}{N_P} \right]$$

$$\mu_e = -k_B T \ln \left[\frac{Z_1^e}{N_e} \right]$$

Thus we have

$$\frac{N_P N_e}{N_H} e^{\beta R} = \frac{Z_1^P Z_1^e}{Z_1^H} = Z_1^e = V \left(\frac{m k_B T}{2\pi \hbar^2} \right)^{3/2}$$

or

$$\frac{n_P n_e}{n_H} = n_Q e^{-\beta R} = \left(\frac{m k_B T}{2\pi \hbar^2} \right)^{3/2} e^{-\beta R}$$

since $Z_1^P = Z_1^H$, where $n_P = \frac{N_P}{V}$, $n_e = \frac{N_e}{V}$, $n_H = \frac{N_H}{V}$, and

$$n_Q = \frac{1}{\lambda_{th}^3} = \left(\frac{m k_B T}{2\pi \hbar^2} \right)^{3/2}$$

We assume that n is the number density of nucleus.

$$n = n_H + n_P, \quad n_P = n_e = ny$$

$$n_H = n - n_P = n(1 - y)$$

Then we have

$$\frac{n^2 y^2}{n(1-y)} = n_Q \exp(-\beta R)$$

$$\begin{aligned} \frac{y^2}{1-y} &= \frac{1}{n} n_Q \exp\left(-\frac{R}{k_B T}\right) \\ &= \frac{1}{n} \left(\frac{2\pi m k_B T}{h^2}\right)^{3/2} \exp\left(-\frac{R}{k_B T}\right) \end{aligned}$$

where $R = 13.6 \text{ eV}$. $n = 10^{14} \text{ cm}^{-3}$.

$$x = \frac{T(K)}{10^4}.$$

When $f(x=1) = 3.37886$, we have $y = 0.807174$.

We make a ContourPlot of y vs x ;

$$\frac{y^2}{1-y} = f(x)$$

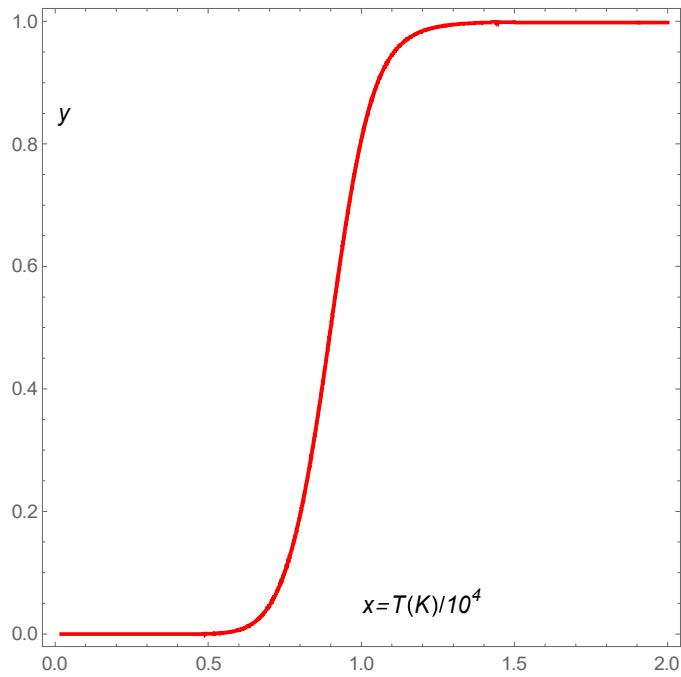

Fig. $n_p / n = y$ vs $x = T(K) / 10^4$.

The fraction y increases with increasing temperature T .
